Dear Editor-in-Chief and Editorial Office,

Please consider the enclosed manuscript, “Reconstructable, privacy-preserving provenance for FHIR-to-large language model clinical transactions: a protocol demonstration,” as an Original Research Manuscript in *Computer Methods and Programs in Biomedicine* under the subscription route (no author publication fee).

CMPB publishes computing methods and application-software design for biomedical informatics. This work describes a bounded recording and verification method for one synthetic FHIR-to-LLM transaction: a data/proof split, typed events, structured rationale without hidden chain-of-thought, and an in-repository verifier. What is already known includes FHIR Provenance/AuditEvent projections and tamper-evident logging primitives; clinical LLM studies have focused mainly on accuracy. What this study adds is reconstructability, mutation detection, access outcomes, and capture overhead versus an identical unrecorded clinical workflow on synthetic fixtures. The contribution is an integration of known primitives, not a new cryptographic construction.

This manuscript is original and is not under consideration elsewhere. A related manuscript by the same author on retrieval-augmented FHIR translation addresses a different research question.

No human subjects or identifiable clinical records were used.

Sincerely,

Satya Venkata Ranga Janaki Sriram
Mentey
